```
EBV netCDF properties-class EBV\ netCDF\ properties\ class\ (S4)
```

Description

EBV netCDF properties class (S4)

Value

S4 class containing the EBV netCDF properties

ebvcube 3

Slots

general Named list. Elements: title, description, ebv_class, ebv_name, ebv_domain, references, source, project_name, project_url, creator_name, creator_institution, creator_email, contributor_name, publisher_name, publisher_institution, publisher_email, comment, keywords, id, history, licence, conventions, naming_authority, date_created, date_issued, entity_names, entity_type, entity_scope, entity_classification_name, entity_classification_url, taxonomy, taxonomy_lsid

spatial Named list. Elements: wkt2, epsg, extent, resolution, crs_units, dimensions, scope, description

temporal Named list. Elements: resolution, units, timesteps, dates

metric Named list. Elements: name, description

scenario Named list. Elements: name, description

ebv_cube Named list. Elements: units, coverage_content_type, fillvalue, type

Note

If the properties class holds e.g. no scenario information this is indicated with an element called status in the list.

If you read an EBV netCDF based on an older standard, the properties will differ from the definition above. If the dataset does not encompass taxonomic info, the 'taxonomy' is NA. Besides, even if a dataset encompasses the taxonomy information, the 'taxonomy_lsid' can be NA.

ebvcube

Working with netCDF for Essential Biodiversity Variables

Description

This package can be used to easily access the data of the EBV netCDFs which can be downloaded from the Geobon Portal. It also provides some basic visualization of the data. Advanced users can build their own netCDFs with the EBV standard using this package.

Details

This package contains three main usecases: accessing the data, visualising it and creating your own data in the EBV netCDF standard.

ebv_add_data

Add data to your EBV netCDF

Description

Add data to your EBV netCDF from GeoTiffs or in-memory arrays. First, create a new EBV netCDF using ebv_create().

4 ebv_add_data

Usage

```
ebv_add_data(
   filepath_nc,
   datacubepath = NULL,
   entity = NULL,
   timestep = 1,
   data,
   band = 1,
   scenario = NULL,
   metric = NULL,
   ignore_RAM = FALSE,
   verbose = TRUE
)
```

Arguments

filepath_nc Character. Path to the self-created netCDF file.

datacubepath Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()).

Alternatively, you can use the scenario and metric argument to define which

cube you want to access.

entity Character or Integer. Default is NULL. If the structure is 3D, the entity argument

is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs. The character string can be obtained using <code>ebv_properties()</code>. Choose the entity you are interested in

from the slot general and the list item entity_names.

timestep Integer or character. Default: 1. Define to which timestep or timesteps the data

should be added. If several timesteps are given they have to be in a continuous and in order. Meaning c(4,5,6) is right but c(2,5,6) is wrong. Alternatively you can provide a date or list of dates in ISO format, such as '2015-01-01' (also in

order).

data Character or matrix or array. If character: Path to the GeoTiff file containing the

data. Ending needs to be *.tif. If matrix or array: in-memory object holding the

data.

band Integer. Default: 1. Define which band(s) to read from GeoTiff. Can be several.

Don't have to be in order as the timesteps definition requires.

scenario Character or integer. Optional. Default: NULL. Define the scenario you want to

access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or

number (integer), use ebv_datacubepaths().

metric Character or integer. Optional. Define the metric you want to access. You

can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number

(integer), use ebv_datacubepaths().

ignore_RAM Logical. Default: FALSE. Checks if there is enough space in your memory to

read the data. Can be switched off (set to TRUE). Ignore this argument when

you give an array or a matrix for 'data' (it will do nothing).

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

ebv_analyse 5

Value

Adds data to the EBV netCDF. Check your results using ebv_read() and/or ebv_analyse() and/or ebv_map() and/or ebv_trend().

Note

If the data exceeds your memory the RAM check will throw an error. No block-processing or other method implemented so far. Move to a machine with more capacities if needed.

Examples

```
#set path to EBV netCDF
file <- system.file(file.path("extdata","test.nc"), package="ebvcube")</pre>
#get all datacubepaths of EBV netCDF
datacubepaths <- ebv_datacubepaths(file, verbose=FALSE)</pre>
#set path to GeoTiff with data
tif <- system.file(file.path("extdata","entity1.tif"), package="ebvcube")</pre>
# add data to the timestep 1, 2 and 3 using the first three bands of the GeoTiff
## Not run:
#use datacubepath argument and define timestep by integer
ebv_add_data(filepath_nc = file, datacubepath = datacubepaths[1,1],
             entity = 1, timestep = 1:3, data = tif, band = 1:3)
#use metric argument and define timestep by ISO-format
ebv_add_data(filepath_nc = file, entity = 1,
             timestep = paste0(as.character(seq(1900,1920,10)), '-01-01'),
             metric = 1, data = tif, band = 1:3, verbose = FALSE)
## End(Not run)
```

ebv_analyse

Get a simple explorative analysis of an EBV netCDF datacube

Description

Get basic measurements of the data, including min, max, mean, sd, n, #NAs, q25, q50, q75 (no mean for categorical data).

Usage

```
ebv_analyse(
   filepath,
   datacubepath = NULL,
   entity = NULL,
   timestep = 1,
   subset = NULL,
   touches = TRUE,
   epsg = 4326,
   scenario = NULL,
   metric = NULL,
   numerical = TRUE,
   na_rm = TRUE,
   verbose = TRUE
)
```

6 ebv_analyse

Arguments

filepath	Character. Path to the netCDF file.
datacubepath	Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()). Alternatively, you can use the scenario and metric argument to define which cube you want to access.
entity	Character or Integer. Default is NULL. If the structure is 3D, the entity argument is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs.
timestep	Integer or character. Select one or several timestep(s). Either provide an integer value or list of values that refer(s) to the index of the timestep(s) (minimum value: 1) or provide a date or list of dates in ISO format, such as '2015-01-01'.
subset	Optional if you want measurements on a smaller subset. Possible via the path to a shapefile (character) or the indication of a bounding box (vector of four numeric values) defining the subset. Else the whole area is analysed.
touches	Logical. Optional. Default: TRUE. Only relevant if the subset is indicated by a shapefile. See ebv_read_shp().
epsg	Numeric. Optional. Only relevant if the subset is indicated by a bounding box and the coordinate reference system differs from WGS84. See ebv_read_bb().
scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or number (integer), use ebv_datacubepaths().
metric	Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number (integer), use ebv_datacubepaths().
numerical	Logical. Default: TRUE. Change to FALSE if the data covered by the netCDF contains categorical data.
na_rm	Logical. Default: TRUE. NA values are removed in the analysis. Change to FALSE to include NAs.
verbose	Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Returns a named list containing the measurements.

See Also

```
ebv_read_bb() and ebv_read_shp() for the usage of subsets.
```

```
#set path to EBV netCDF
file <- system.file(file.path("extdata","martins_comcom_subset.nc"), package="ebvcube")
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file, verbose=FALSE)
#set path to shp file
shp_path <- system.file(file.path("extdata","cameroon.shp"), package="ebvcube")</pre>
```

ebv_attribute 7

ebv_attribute

Write a new attribute value to an EBV netCDF

Description

Write a new attribute value to an EBV netCDF. Not all attributes can be changed. Some are always created automatically, e.g. the attributes belonging to the crs, time and var_entity datasets. In this case you have to re-create the netCDF file.

Usage

```
ebv_attribute(
   filepath,
   attribute_name,
   value,
   levelpath = NULL,
   verbose = TRUE
)
```

Arguments

filepath Character. Path to the netCDF file.

attribute_name Character. Name of the attribute that should be changed.

value New value that should be assigned to the attribute.

levelpath Character. Default: NULL. Indicates the location of the attribute. The default

means that the attribute is located at a global level. If the attribute is located at the datacubelevel just add the datacubepath, e.g. metric_1/ebv_cube. For the metric level the value may be 'metric_1' or 'scenario_1/metric_1'. This path

depends on whether the netCDF hierarchy has scenarios or not.

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Adds the new value to the attribute. Check your results using ebv_properties().

8 ebv_create

Note

You can change the ebv_class and the ebv_name. In this case you need to change the ebv_class first. Don't forget to change the ebv_name accordingly!

Examples

```
#set path to EBV netCDF file <-
system.file(file.path("extdata", "baisero_spepop_id5_20220405_v1_empty.nc"),
package="ebvcube")
## Not run:
try({
#change the standard_name of the metric
attribute1 <- 'standard_name'</pre>
value1 <- 'habitat availability'</pre>
level1 <- 'scenario_1/metric_1'</pre>
ebv_attribute(filepath = file, attribute_name = attribute1,
              value = value1, level = level1)
#change the units of the ebv_cube
attribute2 <- 'units'
value2 <- 'Land-use of 5,090 mammals calculated in sqkm'</pre>
level2 <- 'scenario_1/metric_1/ebv_cube' #equal to the datacubepath</pre>
ebv_attribute(filepath = file, attribute_name = attribute2,
              value = value2, level = level2)
#change the name of the creator at the global level
attribute3 <- 'creator_name'
value3 <- 'Jane Doe'
ebv_attribute(filepath = file, attribute_name = attribute3,
              value = value3)
}, TRUE)
## End(Not run)
```

ebv_create

Create an EBV netCDF

Description

Create the core structure of the EBV netCDF based on the json from the EBV Data Portal. Data will be added afterwards using ebv_add_data().

Usage

```
ebv_create(
   jsonpath,
   outputpath,
   entities,
   epsg = 4326,
   extent = c(-180, 180, -90, 90),
   resolution = c(1, 1),
   timesteps = NULL,
```

ebv_create 9

```
fillvalue = NULL,
prec = "double",
sep = ",",
force_4D = TRUE,
overwrite = FALSE,
verbose = TRUE
```

Arguments

jsonpath Character. Path to the json file downloaded from the EBV Data Portal. Login to

the page and click on 'Uploads' and 'New Upload' to start the process.

outputpath Character. Set path where the netCDF file should be created.

entities Character string or vector of character strings. In case of single character string:

Path to the csv table holding the entity names. Default: comma-separated delimiter, else change the sep argument accordingly. Should have only one column, each row is the name of one entity. In case of vector of character strings: Vector

holding the entity names.

epsg Integer. Default: 4326 (WGS84). Defines the coordinate reference system via

the corresponding epsg code.

extent Numeric. Default: c(-180,180,-90,90). Defines the extent of the data: c(xmin,

xmax, ymin, ymax).

resolution Numerical. Vector of two numerical values defining the longitudinal and latitu-

dinal resolution of the pixel: c(lon,lat).

timesteps Character. Vector of the timesteps in the dataset. Default: NULL - in this case

the time will be calculated from the start-, endpoint and temporal resolution given in the metadata file (json). Else, the dates must be given in in ISO format

'YYYY-MM-DD' or shortened 'YYYY' in case of yearly timesteps.

fillvalue Numeric. Value of the missing data in the array. Not mandatory but should be

defined!

prec Character. Default: 'double'. Precision of the data set. Valid options: 'short'

'integer' 'float' 'double' 'char' 'byte'.

sep Character. Default: ','. If the delimiter of the csv specifying the entity-names

differs from the default, indicate here.

force_4D Logical. Default is TRUE. If the argument is TRUE, there will be 4D cubes (lon,

lat, time, entity) per metric. If this argument is changed to FALSE, there will be 3D cubes (lon, lat, time) per entity (per metric). So the latter yields a higher amount of cubes and does not bundle all information per metric. In the future the standard will be restricted to the 4D version. Recommendation: go with the

4D cubes!

overwrite Logical. Default: FALSE. Set to TRUE to overwrite the output file defined by

'outputpath'.

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Creates the netCDF file at the 'outputpath' location.

Note

To check out the results take a look at your netCDF file with Panoply provided by the NASA.

10 ebv_create_taxonomy

Examples

ebv_create_taxonomy

Create an EBV netCDF with taxonomy

Description

Create the core structure of the EBV netCDF based on the json from the EBV Data Portal. Additionally, you can add the hierarchy of the taxonomy. This is not provided in the ebv_create() function. Use the ebv_create() function if your dataset holds no taxonomic information. Data will be added afterwards using ebv_add_data().

Usage

```
ebv_create_taxonomy(
  jsonpath,
 outputpath,
  taxonomy,
  lsid = FALSE,
  epsg = 4326,
  extent = c(-180, 180, -90, 90),
 resolution = c(1, 1),
  timesteps = NULL,
  fillvalue = NULL,
 prec = "double",
  sep = ",",
  force_4D = TRUE,
 overwrite = FALSE,
  verbose = TRUE
)
```

Arguments

jsonpath Character. Path to the json file downloaded from the EBV Data Portal. Login to

the page and click on 'Uploads' and 'New Upload' to start the process.

outputpath Character. Set path where the netCDF file should be created.

ebv_create_taxonomy 11

taxonomy Character. Path to the csv table holding the taxonomy. Default: comma-separated delimiter, else change the sep argument accordingly. The csv needs to have the following structure: The header displays the names of the different taxon levels ordered from the highest level to the lowest, e.g. "Order", "Family", "Genus", "Species". The last column (if 1sid=FALSE) is equivalent to the entity argument in the ebv_create() function. Each row of the csv corresponds to a unique entity. In case the 1sid argument (see below) is set to the TRUE, this table gets an additional last column which holds the lsid per entity - in this case the second last column contains the entity names, e.g. the following column order: "Order", "Family", "Genus", "Species", "Isid". Logical. Default: FALSE. Set to TRUE if the last column in your taxonomy lsid csv file defines the lsid for each entity. For more info check CF convention 1.8: Taxon Names and Identifiers. Integer. Default: 4326 (WGS84). Defines the coordinate reference system via epsg the corresponding epsg code. Numeric. Default: c(-180,180,-90,90). Defines the extent of the data: c(xmin, extent xmax, ymin, ymax). Numerical. Vector of two numerical values defining the longitudinal and latituresolution dinal resolution of the pixel: c(lon,lat). timesteps Character. Vector of the timesteps in the dataset. Default: NULL - in this case

Character. Vector of the timesteps in the dataset. Default: NULL - in this case the time will be calculated from the start-, endpoint and temporal resolution given in the metadata file (json). Else, the dates must be given in in ISO format 'YYYY-MM-DD' or shortened 'YYYY' in case of yearly timesteps.

fillvalue Numeric. Value of the missing data in the array. Not mandatory but should be defined!

Character. Default: 'double'. Precision of the data set. Valid options: 'short' 'integer' 'float' 'double' 'char' 'byte'.

sep Character. Default: ','. If the delimiter of the csv specifying the entity-names differs from the default, indicate here.

Logical. Default is TRUE. If the argument is TRUE, there will be 4D cubes (lon, lat, time, entity) per metric. If this argument is changed to FALSE, there will be 3D cubes (lon, lat, time) per entity (per metric). So the latter yields a higher amount of cubes and does not bundle all information per metric. In the future the standard will be restricted to the 4D version. Recommendation: go with the

4D cubes!

Logical. Default: FALSE. Set to TRUE to overwrite the output file defined by

'outputpath'

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE. #'

@note To check out the results take a look at your netCDF file with Panoply

provided by the NASA.

Value

prec

force_4D

overwrite

Creates the netCDF file at the 'outputpath' location including the taxonomy information.

Note

You can check the taxonomy info with ebv_properties() in the slot 'general' under the name 'taxonomy' and 'taxonomy_lsid'.

12 ebv_datacubepaths

Examples

ebv_datacubepaths

Get datacubepaths of EBV netCDF

Description

Get the paths to the datacubes of the EBV netCDF to access the data.

Usage

```
ebv_datacubepaths(filepath, verbose = TRUE)
```

Arguments

filepath Character. Path to the netCDF file.

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Dataframe containing the paths to access the datacubes and descriptions of scenario, metric and entity if existing.

```
#set path to EBV netCDF
file <- system.file(file.path("extdata","martins_comcom_subset.nc"), package="ebvcube")
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file)</pre>
```

ebv_download 13

ebv_download	Download an EBV netCDF file

Description

Returns the list of all available data sets at the EBV Portal if you no arguments are given. If an ID is given, the corresponding file (netCDF) and its metadata (json file) will be downloaded to the given output directory.

Usage

```
ebv_download(id = NULL, outputdir, overwrite = FALSE, verbose = TRUE)
```

Arguments

id	Integer or Character. There are three option to identify the dataset to be downloaded. (1) It can be a single integer value representing the ID of the dataset. (2) It can be a character string representing the title of the data set. (3) It can be a character string representing the DOI of the dataset in the format '10.25829/f2rdp4' (Dataset 'Habitat availability for African great apes' by Jessica Junker from the EBV Data Portal). All three identifier can be retrieved by running ebv_download() without any arguments which returns a data.frame of all available data sets and their ID, title and DOI.
outputdir	Character. Output directory of the downloaded files.
overwrite	Logical. Default: FALSE. Set to TRUE if you want to overwrite the netCDF and json.
verbose	Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Downloads a netCDF and json file (ACDD metadata) to the given output directory. If run empty returns a data.frame of all available data sets and their ID, title and DOI.

```
#get all available datasets
datasets <- ebv_download()

ebv_download(id = datasets$id[1], outputdir = tempdir(), overwrite=TRUE, verbose=FALSE)</pre>
```

14 ebv_map

ebv_map

Map plot of an EBV netCDF

Description

Map plot of the data of one timestep in one datacube of an EBV netCDF.

Usage

```
ebv_map(
   filepath,
   datacubepath = NULL,
   entity = NULL,
   timestep = 1,
   countries = TRUE,
   col_rev = FALSE,
   classes = 5,
   scenario = NULL,
   metric = NULL,
   all_data = FALSE,
   ignore_RAM = FALSE,
   verbose = TRUE
)
```

Arguments

filepath	Character. Path to the netCDF file.
datacubepath	Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()). Alternatively, you can use the scenario and metric argument to define which cube you want to access.
entity	Character or Integer. Default is NULL. If the structure is 3D, the entity argument is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs.
timestep	Integer or character. Select a timestep. Either provide an integer value that refers to the index of the timestep (minimum value: 1) or provide a date in ISO format, such as '2015-01-01'.
countries	Logical. Default: TRUE. Simple country outlines will be plotted on top of the raster data. Disable by setting this option to FALSE.
col_rev	Logical. Default: FALSE Set to TRUE if you want the color ramp to be the other way around.
classes	Integer. Default: 5. Define the amount of classes (quantiles) for the symbology. Currently restricted to maximum 11 classes (allowed maximum for palette RdYlBu is 11).
scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario.

number (integer), use ebv_datacubepaths().

nario as a character string. To check the available scenarios and their name or

ebv_properties 15

metric Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number

(integer), use ebv_datacubepaths().

all_data Logical. Default: FALSE. The quantiles are based on the one timestep you

chose (default). If you want include the full data of the datacube to produce several maps that are based on the same color scale, set this argument to TRUE (to allow for viusual comparison between entities or timesteps. Does not cover

different datacubes.)

ignore_RAM Logical. Default: FALSE. Checks if there is enough space in your memory to

read the data. Can be switched off (set to TRUE).

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Plots a map.

Examples

ebv_properties

Read properties of EBV netCDF

Description

Structured access to all attributes of the netCDF file.

Usage

```
ebv_properties(
  filepath,
  datacubepath = NULL,
  scenario = NULL,
  metric = NULL,
  verbose = TRUE
)
```

16 ebv_read

Arguments

filepath Character. Path to the netCDF file.

datacubepath Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()).

Alternatively, you can use the scenario and metric argument to define which

cube you want to access.

scenario Character or integer. Optional. Default: NULL. Define the scenario you want to

access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or

number (integer), use ebv_datacubepaths().

metric Character or integer. Optional. Define the metric you want to access. You

can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number

(integer), use ebv_datacubepaths().

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

S4 class containing information about file or file and datacube depending on input.

Examples

```
#define path to EBV netCDF
file <- system.file(file.path("extdata","martins_comcom_subset.nc"), package="ebvcube")
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file, verbose=FALSE)

#get properties only for the file
prop_file <- ebv_properties(file)
#get properties for the file and a specific datacube - use datacubepath
prop_dc <- ebv_properties(file, datacubepath = datacubes[1,1])
#get properties for the file and a specific datacube - use scenario & metric
#note: this dataset has no scenario -> only metric is defined
prop_dc <- ebv_properties(file, metric = 2)</pre>
```

ebv_read

Read data from an EBV netCDF

Description

Read one or more layers from one datacube of the netCDF file. Decide between in-memory array, in-memory SpatRaster or an array-like object (DelayedMatrix) pointing to the on-disk netCDF file. The latter is useful for data that exceeds your memory.

Usage

```
ebv_read(
  filepath,
  datacubepath = NULL,
  entity = NULL,
  timestep = 1,
```

ebv_read 17

```
type = "r",
scenario = NULL,
metric = NULL,
sparse = FALSE,
ignore_RAM = FALSE,
verbose = FALSE
```

Arguments

filepath	Character. Path to the netCDF file.
datacubepath	Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()). Alternatively, you can use the scenario and metric argument to define which cube you want to access.
entity	Character or Integer. Default is NULL. If the structure is 3D, the entity argument is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs.
timestep	Integer or character. Select one or several timestep(s). Either provide an integer value or list of values that refer(s) to the index of the timestep(s) (minimum value: 1) or provide a date or list of dates in ISO format, such as '2015-01-01'.
type	Character. Choose between 'a', 'r' and 'da'. The first returns an array or matrix object. The 'r' indicates that a SpatRaster object from the terra package will be returned (default). The latter ('da') returns a DelayedArray or DelayedMatrix object.
scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or number (integer), use ebv_datacubepaths().
metric	Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number (integer), use ebv_datacubepaths().
sparse	Logical. Default: FALSE. Set to TRUE if the data contains a lot empty raster cells. Only relevant for DelayedArray return value.
ignore_RAM	Logical. Default: FALSE. Checks if there is enough space in your memory to read the data. Can be switched off (set to TRUE).
verbose	Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Array, SpatRaster or DelayedArray object containing the data of the corresponding datacube and timestep(s).

Note

For working with the DelayedMatrix take a look at DelayedArray::DelayedArray() and the DelayedArray-utils.

18 ebv_read_bb

Examples

ebv_read_bb

Read subset (bounding box) of one datacube of an EBV netCDF

Description

Read a subset of one or more layers from one datacube of the NetCDF file. Subset definition by a bounding box.

Usage

```
ebv_read_bb(
   filepath,
   datacubepath = NULL,
   entity = NULL,
   timestep = 1,
   bb,
   outputpath = NULL,
   epsg = 4326,
   scenario = NULL,
   metric = NULL,
   overwrite = FALSE,
   ignore_RAM = FALSE,
   verbose = TRUE
)
```

Arguments

filepath Character. Path to the netCDF file.

 ${\tt datacubepath} \qquad {\tt Character.\ Optional.\ Default:\ NULL.\ Path\ to\ the\ datacube\ (use\ ebv_datacubepaths\ ()).}$

Alternatively, you can use the scenario and metric argument to define which

cube you want to access.

ebv_read_bb 19

entity	Character or Integer. Default is NULL. If the structure is 3D, the entity argument is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs.
timestep	Integer or character. Select one or several timestep(s). Either provide an integer value or list of values that refer(s) to the index of the timestep(s) (minimum value: 1) or provide a date or list of dates in ISO format, such as '2015-01-01'.
bb	Integer Vector. Definition of subset by bounding box: c(xmin, xmax, ymin, ymax).
outputpath	Character. Default: NULL, returns the data as a SpatRaster object in memory. Optional: set path to write subset as GeoTiff on disk.
epsg	Integer. Default: 4326 (WGS84). Change accordingly if your bounding box coordinates are based on a different coordinate reference system.
scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or number (integer), use ebv_datacubepaths().
metric	Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number (integer), use ebv_datacubepaths().
overwrite	Logical. Default: FALSE. Set to TRUE to overwrite the outputfile defined by 'outputpath'.
ignore_RAM	Logical. Default: FALSE. Checks if there is enough space in your memory to read the data. Can be switched off (set to TRUE).
verbose	Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Returns a SpatRaster object if no outputpath is given. Otherwise the subset is written onto the disk and the outputpath is returned.

Note

In case the epsg of the Bounding Box and the netCDF differ, the data is returned based on the epsg of the netCDF Dataset.

See Also

ebv_read_shp() for subsetting via shapefile.

```
#set path to EBV netCDF
file <- system.file(file.path("extdata","martins_comcom_subset.nc"), package="ebvcube")
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file, verbose=FALSE)

#set outputpath
out <- file.path(system.file(package='ebvcube'),"extdata","subset_bb.tif")
#define two different bounding boxes based on different EPSG codes</pre>
```

20 ebv_read_shp

ebv_read_shp

Read subset (shapefile) of one datacube of an EBV netCDF

Description

Read a subset of one or more layers from one datacube of the netCDF file. Subset definition by a shapefile.

Usage

```
ebv_read_shp(
  filepath,
  datacubepath = NULL,
  entity = NULL,
  timestep = 1,
  shp,
  outputpath = NULL,
  touches = TRUE,
  scenario = NULL,
  metric = NULL,
  overwrite = FALSE,
  ignore_RAM = FALSE,
  verbose = TRUE
)
```

Arguments

filepath Character. Path to the netCDF file.

 ${\tt datacubepath} \qquad {\tt Character.\ Optional.\ Default:\ NULL.\ Path\ to\ the\ datacube\ (use\ ebv_datacubepaths\ ()).}$

Alternatively, you can use the scenario and metric argument to define which

cube you want to access.

ebv_read_shp 21

entity	Character or Integer. Default is NULL. If the structure is 3D, the entity argument is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs.
timestep	Integer or character. Select one or several timestep(s). Either provide an integer value or list of values that refer(s) to the index of the timestep(s) (minimum value: 1) or provide a date or list of dates in ISO format, such as '2015-01-01'.
shp	Character. Path to the shapefile defining the subset. Ending needs to be *.shp.
outputpath	Character. Default: NULL, returns the data as a SpatRaster object in memory. Optional: set path to write subset as GeoTiff on disk.
touches	Logical. Default: TRUE, all pixels touched by the polygon(s) will be updated. Set to FALSE to only include pixels that are on the line render path or have center points inside the polygon(s).
scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or number (integer), use ebv_datacubepaths().
metric	Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number (integer), use ebv_datacubepaths().
overwrite	Logical. Default: FALSE. Set to TRUE to overwrite the outputfile defined by 'outputpath'.
ignore_RAM	Logical. Default: FALSE. Checks if there is enough space in your memory to read the data. Can be switched off (set to TRUE).
verbose	Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Returns a SpatRaster object if no output path is given. Otherwise the subset is written onto the disk and the ouput path is returned.

See Also

ebv_read_bb() for subsetting via bounding box.

22 ebv_resample

ebv_resample

Change the resolution of the data of an EBV netCDF

Description

Change the resolution of one datacube of a EBV netCDF based on another EBV netCDF or a given resolution.

Usage

```
ebv_resample(
   filepath_src,
   datacubepath_src = NULL,
   entity_src = NULL,
   timestep_src = 1,
   resolution,
   outputpath,
   method = "bilinear",
   scenario = NULL,
   metric = NULL,
   return_raster = FALSE,
   overwrite = FALSE,
   ignore_RAM = FALSE,
   verbose = TRUE
)
```

Arguments

filepath_src Character. Path to the netCDF file whose resolution should be changed.

datacubepath_src

Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()). Alternatively, you can use the scenario and metric argument to define which

cube you want to access.

entity_src Character or Integer. Default is NULL. If the structure is 3D, the entity argument

is set to NULL. Else, a character string or single integer value must indicate the

entity of the 4D structure of the EBV netCDFs.

timestep_src Integer or character. Select one or several timestep(s). Either provide an integer

value or list of values that refer(s) to the index of the timestep(s) (minimum value: 1) or provide a date or list of dates in ISO format, such as '2015-01-01'.

resolution Character or Numeric. Either the path to an EBV netCDF file that determines the

resolution (character) or the resolution defined directly (numeric). The vector defining the resolution directly must contain three elements: the x-resolution, the y-resolution and the corresponding EPSG code, e.g. c(0.25, 0.25, 4326).

outputpath Character. Set path to write data as GeoTiff on disk.

method Character. Default: bilinear. Define resampling method. Choose from: "near", "bilinear", "cubic",

"cubicspline", "lanczos", "sum", "min", "q1", "med", "q3", "max", "average", "mode" and "rms". For categorical data, use 'near'. Based on terra::project().

ebv_resample 23

scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or number (integer), use ebv_datacubepaths().
metric	Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number (integer), use ebv_datacubepaths().
return_raster	Logical. Default: FALSE. Set to TRUE to directly get the corresponding SpatRaster object.
overwrite	Logical. Default: FALSE. Set to TRUE to overwrite the output file defined by 'outputpath'.
ignore_RAM	Logical. Default: FALSE. Checks if there is enough space in your memory to read the data. Can be switched off (set to TRUE).
verbose	Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Default: returns the output path of the GeoTiff with the new resolution. Optional: return the SpatRaster object with the new resolution.

```
#set path to EBV netCDF
file <- system.file(file.path("extdata", "martins_comcom_subset.nc"),</pre>
                     package="ebvcube")
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file, verbose=FALSE)</pre>
#define different resolutions
res1 <- system.file(file.path("extdata",</pre>
        "baisero_spepop_id5_20220405_v1_empty.nc"), package="ebvcube")
res2 <- c(0.5, 0.5, 4326)
#define output path
out <- file.path(system.file(package='ebvcube'), "extdata", "changeRes.tif")</pre>
## Not run:
\#resample defining the resolution and EPSG code by hand - return SpatRaster
data_raster <- ebv_resample(filepath_src = file, datacubepath_src = datacubes[1,1],</pre>
                             entity_src=1, timestep_src = 1, resolution = res2,
                             outputpath = out, method='near', return_raster=TRUE,
                             overwrite=TRUE)
#resample using a netCDF file - return GeoTiff
ebv_resample(filepath_src = file, datacubepath_src = datacubes[1,1],
             entity_src=1, timestep_src = 1, resolution = res1,
             outputpath = out, overwrite=TRUE)
## End(Not run)
```

24 ebv_trend

ebv_trend

Plot the trend of an EBV netCDF

Description

Plot the trend of one datacube of a EBV netCDF over time (x-axis). Different options can be chosen based on the method argument.

Usage

```
ebv_trend(
  filepath,
  datacubepath = NULL,
  entity = NULL,
  method = "mean",
  subset = NULL,
  color = "dodgerblue4",
  touches = TRUE,
  scenario = NULL,
  metric = NULL,
  verbose = TRUE
)
```

Arguments

verbose

filepath	Character. Path to the netCDF file.
datacubepath	Character. Optional. Default: NULL. Path to the datacube (use ebv_datacubepaths()). Alternatively, you can use the scenario and metric argument to define which cube you want to access.
entity	Character or Integer. Default is NULL. If the structure is 3D, the entity argument is set to NULL. Else, a character string or single integer value must indicate the entity of the 4D structure of the EBV netCDFs.
method	Character. Default: mean. Choose one of the following options for different plots: mean, min, max, boxplot. See Note for more
subset	Character. Default: NULL. If you want to look at the trend for a spatial subset, define the path to the shapefile encompassing the area. Ending needs to be *.shp.
color	Character. Default: dodgerblue4. Change to any color known by R grDevices::colors()
touches	Logical. Optional. Default: TRUE. Only relevant if the subset is indicated by a shapefile. See ebv_read_shp().
scenario	Character or integer. Optional. Default: NULL. Define the scenario you want to access. If the EBV netCDF has no scenarios, leave the default value (NULL). You can use an integer value defining the scenario or give the name of the scenario as a character string. To check the available scenarios and their name or number (integer), use ebv_datacubepaths().
metric	Character or integer. Optional. Define the metric you want to access. You can use an integer value defining the metric or give the name of the scenario as a character string. To check the available metrics and their name or number (integer), use ebv_datacubepaths().

Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

ebv_write 25

Value

Returns plots and eventually values based on the method argument. See Note for more information

Note

More information on the method argument: using mean will result in a plot of the mean over time, additionally a vector of the mean values is returned. If the data encompasses only one timestep a single mean is returned. Corresponding behavior can be expected for min and max. The boxplot option results in boxplots over time (no values are returned).

Examples

```
#set path to EBV netCDF
file <- system.file(file.path("extdata","martins_comcom_subset.nc"), package="ebvcube")
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file, verbose=FALSE)

#plot the change of the mean over time of the first datacube
ebv_trend(filepath = file, datacubepath = datacubes[1,1], entity = 1)</pre>
```

ebv_write

Write the extracted data on your disk as a GeoTiff

Description

After you extracted data from the EBV netCDF and worked with it this function gives you the possibility to write it to disk as a GeoTiff.

Usage

```
ebv_write(
  data,
  outputpath,
  epsg = 4326,
  extent = c(-180, 180, -90, 90),
  type = "FLT8S",
  overwrite = FALSE,
  verbose = TRUE
)
```

Arguments

Your data object. May be SpatRaster, array, DelayedMatrix or list of Delayed-Matrix (see return values of ebv_read())

Outputpath Character. Set the path where you want to write the data to disk as a GeoTiff. Ending needs to be *.tif.

epsg Integer. Default: 4326 (WGS84). Defines the coordinate reference system via the corresponding epsg code.

26 world_boundaries

extent Numeric. Default: c(-180,180,-90,90). Defines the extent of the data: c(xmin,

xmax, ymin, ymax).

type Character. Default is FLT8S Indicate the datatype of the GeoTiff file. Possible

values: INT1S, INT2S, INT2U, INT4S, INT4U, FLT4S, FLT8S.

overwrite Locigal. Default: FALSE. Set to TRUE to overwrite the outputfile defined by

'outputpath'.

verbose Logical. Default: TRUE. Turn off additional prints by setting it to FALSE.

Value

Returns the outputpath.

Note

If the nodata value of your data is not detected correctly, this could be due to the wrong choice of the datatype (type argument).

Examples

```
#set path to EBV netCDF
file <- system.file(file.path("extdata","martins_comcom_subset.nc"), package="ebvcube")</pre>
#get all datacubepaths of EBV netCDF
datacubes <- ebv_datacubepaths(file, verbose=FALSE)</pre>
## Not run:
#read data
data <- ebv_read(filepath = file, datacubepath = datacubes[1,1], timestep = 1, entity = 1)</pre>
# HERE YOU CAN WORK WITH YOUR DATA
#write data to disk as GeoTiff
out <- file.path(system.file(package='ebvcube'), "extdata", "write_data.tif")</pre>
ebv_write(data = data, outputpath = out, overwrite = TRUE)
#read a subset
data_bb <- ebv_read_bb(filepath = file, datacubepath = datacubes[1,1],</pre>
                        entity = 1, timestep = 1:3, bb = c(-26, 64, 30, 38))
#write subset to disk as GeoTiff
ebv_write(data = data_bb, outputpath = out, extent = c(-26, 64, 30, 38), overwrite = TRUE)
## End(Not run)
```

world_boundaries

Simple outlines of world countries

Description

Simple outlines of world countries

Usage

```
world_boundaries
```

world_boundaries 27

Format

A data.frame with 177 elements and geometry as WKT

Source

Data downloaded from Natural Earth. Used version 4.0.0 and reduced attributes.
